

**PROTECTIVE RELAYING EQUIPMENT COMPONENTS****TYPE CFD  
HIGH-SPEED DIFFERENTIAL RELAYS**

Increasing slope (product-restraint) characteristic

For differential protection of a-c generators, frequency converters, synchronous condensers, and motors.

CFD12B single-phase current-differential relay.

**GENERAL**  **ELECTRIC**

## FEATURES . . . . .

High-speed differential protection for both phase and ground faults.

Product-restraint insures freedom from tripping on external short circuits.

Modern design, utilizing induction-cylinder principle, provides smooth high torque.

Silver-to-silver nonbouncing contacts are easily visible to permit ready inspection.

Spring-mounted jewel bearing reduces friction and minimizes shocks.

All means for making adjustments are readily accessible.

Relays are dustproof.

Drawout construction, for semiflush or surface mounting.

## RATINGS . . . . .

Continuous Rating in Amperes	Frequency in Cycles	Minimum Pickup Amperes	Contacts Normally Open	Target Amperes	Model No. (Single-phase)	Approx Wt in lb

\* For application to machines of other than 60 cycles, refer inquiry to the Switchgear Sales Division, Philadelphia Works.

## APPLICATION . . . . .

Differential protection should be used with attended and unattended machines, whether or not the machine neutral is grounded, and whether or not the machine is connected to a grounded neutral source. This type of protection is recommended for all generators rated 4160 volts and higher, or 1000 kva and above; for generators rated 2200 volts and higher above 500 kva; for motors and synchronous condensers 1500 hp (or kva) and larger if the voltage is 4160 volts or below; and for motors and synchronous condensers rated 501 hp (or kva) and larger if the voltage is above 4160 volts. Differential protection using high-speed Type CFD relays is recommended for all generators rated 2000 kva and above, and for motors and synchronous condensers rated 3000 hp (or kva) and larger.

All General Electric a-c machines with ratings for which differential relaying is recommended in accordance with the above paragraph normally have both ends of each winding brought out to separate terminals. Machines for lower voltages or those having lower hp or kva ratings may not have such provision unless it is definitely specified.

Differential protection is also recommended for smaller machines than those listed above when such machines operate in parallel on the same bus with differentially protected machines. If a fault occurring in a small machine is not promptly removed, it may prove just as detrimental to service as a similar fault occurring in a large machine. Also, differential protection may be necessary for small machines on the basis of the importance of the machine to the system and on the degree of relaying that is required for a particular installation.

The CFD relays function on the product-restraint principle, which gives very little, or zero, restraining torque on single-end-feed internal faults, and an operating torque from the restraint coils on internal faults, with an external source of power. The relay gives sensitive operation over the normal current range, and has an increasing slope characteristic, which prevents undesired operation on excessive through currents.

These relays provide protection against phase-to-phase and phase-to-ground short circuits which produce more than a certain minimum amount of current;

they will not protect against open circuits, or turn-to-turn short circuits. If the neutral of the system is not grounded, protection against grounds in the machine winding is provided only upon the occurrence of a second ground in another phase of the system.

With zero neutral impedance, differential protective equipment will function on ground short circuits in any part of the winding, except a small portion very close to the neutral point (relay operation, of course, being limited by the magnitude of the short-circuit current and the sensitivity of the relay). If current-limiting devices are used in a grounded neutral, the effectiveness of differential protection in the event of ground short circuits will be diminished, because there will be a somewhat greater portion of the winding next to the neutral point in which ground short circuits will not cause the relay to function.

### Automatic Tripping of Machine Field Switch

When current-differential protection is provided for a-c machines, the field switch should be tripped automatically at the same time that the machine is disconnected from the system. Electrically operated field circuit breakers, or contactors, are generally used for this application, but in some cases manually operated field switches, consisting of an air circuit breaker with a shunt trip and a field discharge clip, are employed.

### Automatic Tripping of Neutral Breakers

If the neutral of a machine is grounded, it is advisable to provide a neutral breaker which can be tripped to open the ground-return circuit of the fault current as quickly as possible. It is usually preferable to trip the neutral breaker, main breaker, and field breaker simultaneously, by means of a hand-reset auxiliary relay.

A ground alarm should be provided in each station. This is usually connected through an auxiliary switch on each of the neutral breakers, so that the alarm will sound only in case all neutral breakers are open.

### Selection of Current Transformers

Current transformers must be accurate within 1 or 2 per cent to twice normal current. Above twice normal current accuracy is not so important.

## OPERATION . . . . .

The operation of these relays can be easily understood by referring to Fig. 1. It will be noted that the secondaries of the current transformers are connected in series with the restraining coils of the relay. The operating coils are connected to an autotransformer which saturates at a relatively low current and provides a greatly increasing slope characteristic as the through-fault current increases.

Under normal conditions the two secondary currents should be equal but they may differ due to current transformer errors. The "difference" or "error" current will flow in the operating coil. For currents up to full load of the machine the error current will be less than the 10 per cent "difference" current required to operate the relay. With an external fault the current in the current transformers can be high and the "error" current may be well over 10 per cent. For this reason, the slope of the relay characteristic is made to increase as the current increases.

If a current flows from the neutral side into the generator and another current flows from the generator to the bus, then the restraining coils produce a

RESTRAINING torque that is proportional to the product of these two currents and the cosine of the angle between them. These are the conditions that will exist during normal operation, during external faults, and during internal faults when the generator continues to supply some current to the bus.

Conversely, if a current flows from the neutral side into the generator and another current flows from the bus into the generator, then the restraining coils produce an OPERATING torque that is proportional to the product of these two currents and the cosine of the angle between them. These are the conditions that will exist during an internal fault when part of the fault current comes from the bus.

This relay restrains in response to the product of the currents entering and leaving the protected zone, and, consequently, the new principle is called "product-restraint." In addition, the relay has a slope which increases very rapidly above approximately twice normal current. This feature eliminates the necessity for close "matching" of the current transformers.

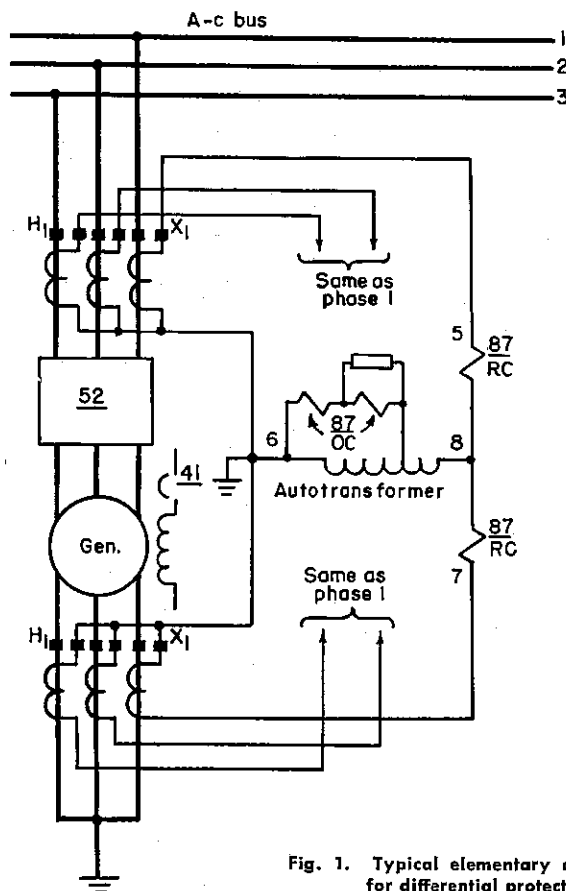

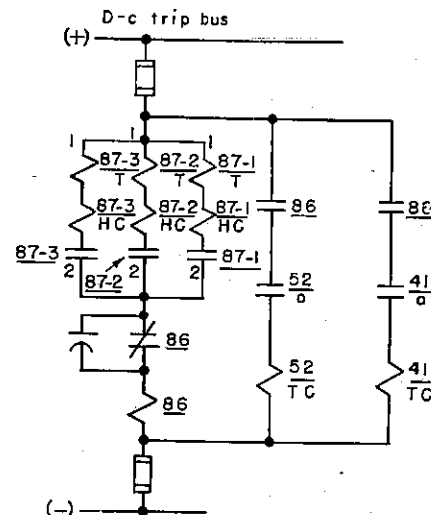

Fig. 1. Typical elementary diagram of three Type CFD12B relays for differential protection of a 3-phase a-c generator

### Device Function Numbers

- 1, 2 etc. — Relay stud numbers
- 41 — Field circuit breaker
- 52 — Power circuit breaker
- 86 — Lockout relay, hand reset, Type HEA
- 87 — Differential relay, Type CFD
- a — Auxiliary switch, closed when circuit breaker is closed.
- HC — Holding coil
- OC — Operating coil
- RC — Restraining coil
- TC — Trip coil
- T — Target

### Type CFD Relays WILL NOT Function for:

- (1) Turn-to-turn faults in the machine windings.
- (2) Open circuits in the machine windings.
- (3) High currents caused by external overloads or short-circuits.
- (4) Line power surges.
- (5) Ground between windings and machine frame, if system is ungrounded, unless a second ground occurs in another phase of the system.

### Type CFD Relays WILL Function for:

- (1) Internal machine faults, except turn-to-turn.
- (2) Faults in primary cables within the protected differential zone.
- (3) Ground short-circuits in any part of the machine winding, except a portion very close to the neutral, provided there is no neutral impedance to limit ground current to a value below the relay pickup calibration.

## CONSTRUCTION . . . . .

**Steel cradle** consists of a light, sturdy structure for supporting the relay unit and the inner contact blocks.

**Control spring** determines the minimum pickup current required to operate the relay and holds the moving contact open when the relay is de-energized.

**Target** displays an orange-colored surface when the relay operates. It is unlatched when tripping current flows through the target coil. Target is reset manually, by means of a push button which extends through lower edge of relay cover.

**Silver-to-silver, nonbouncing contacts** are easily visible to permit ready inspection. Stationary contacts are individually adjustable.

**Shock backstop** reduces tendency of the moving contact to close if the relay, or the panel on which it is mounted, is bumped or jarred.

**Driving element** of the CFD relay consists of a multi-pole stator, a stationary central core, and a cup-like induction rotor, which operates in the air gap between the stator and core. The available poles permit both the differential-operating and the product-restraining functions to be accomplished in a single unit.

**Clips** hold identification or data card.

**Numbering strip** of dull white may be used for circuit identification. Pen or pencil may be used.

**Drawout feature** provides a quick, easy means of removing the unit for inspection or test. By using a test plug the unit can easily be tested without removing it from the panel. For general construction details of the drawout case, refer to publication GEC-456.

**Heating.** Under normal operating conditions, no part of these relays will exceed the heating limits specified by the AIEE and ASA Standards.

**Insulation** is equal to or better than that necessary to meet the requirements of the AIEE and ASA Standards.

**Inner contact block** supports contact fingers of the removable unit. The connecting plug makes connection between these fingers and the contact fingers in the case.

**Latches** at the top and bottom of the cradle lock the relay unit securely in place. The connecting plug must be withdrawn before the bottom latch can be released.

Fig. 2. CFD128 high-speed differential relay unit removed from case

**Resistor**, connected across part of operating coil circuit, produces two fluxes, which are out of phase, from a single current.

**Steel Plate** supports all relay elements.

**Holding Coil** is energized by the tripping current when the contacts close. It holds the contacts in the closed position while the tripping current is flowing.

**Clamp Screw** locks control spring adjusting ring.

**Wiring** has tough Flam-enol covering, for long life and high dielectric strength.

**Target** (see figure 2).

**Front Contact** (see figures 2 and 4).

**Top Latch**, here shown in full open position.

**Autotransformer** saturates at a low current, causing an increasing slope characteristic with increasing fault current.

**Back Contact** may be used to trip a second circuit breaker or connected in parallel with front contact for increased contact life.

**Support** for connection to control spring.

**Set Screw** holds upper steel pivot in place. The permanently lubricated upper bearing consists of a polished steel pin and a bronze guide bearing located in a recess at the top of the shaft. The steel pivot of the lower bearing rotates against a selected sapphire jewel that is expertly ground and polished. The jewel is spring-mounted to protect it from shocks. The jewel screw can be easily removed for inspection.

**Control Spring** adjustment is provided by a ring which is normally clamped. Friction from a spring wire prevents loss of adjustment when clamp screw is loosened.

Fig. 3. Top view of Type CFD12B relay unit removed from case.

## Target and Holding Coils

These coils are available with ratings of 0.2 or 1.0 ampere, as indicated in the table below. The choice of rating depends on the current taken by the tripping circuit. Separate target and holding coils are provided with these relays, as shown by the internal connection diagram.

When it is desirable to adopt one type of relay as standard for use anywhere on a system, relays with 1.0-ampere target and holding coils should be chosen. These relays should also be used where it is impossible to obtain trip coil data, but attention is called to the fact that the target may not operate, if used with trip coils that take less than 1.0 ampere.

Function	AMPERES A-C OR D-C	
	1-amp Target and Holding Coils (0.50 Ohm for Both Coils)	0.2-amp Target and Holding Coils (14 Ohms for Both Coils)
Minimum target operating current . . . .	1.0	0.2
Minimum holding current . . . . .	1.0	0.2
Carry for tripping duty . . . . .	30.0	5.0
Carry continuously . . . . .	2.5	0.5

## Contacts

The CFD relays are supplied with nonbouncing contacts that provide positive contact closing.

The current-closing rating of the contacts is 30 amperes for voltages not exceeding 250 volts. The current-carrying rating is limited by the two forms of target and holding coils, as shown in the table. If the total tripping current exceeds 30 amperes, an auxiliary relay must be used with the CFD relay. After tripping occurs, the tripping circuit must be opened by an auxiliary switch on the circuit breaker, or by other automatic means, because the relay contacts are held closed while the tripping current is flowing.
